Data Wrangling

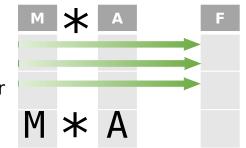

with pandas **Cheat Sheet** In a tidv data ttp://pandas.pydata.orgset:

Data - A foundation for wrangling in pandas

Tidy data complements pandas's vectorized operations. pandas will automatically preserve observations format works as intuitively with

Syntax - Creating

| | a | b | С | |
|---|---|---|----|--|
| 1 | 4 | 7 | 10 | |
| 2 | 5 | 8 | 11 | |
| 3 | 6 | 9 | 12 | |

```
df = pd.DataFrame(
          {"a" : [4 ,5, 6],
           "b" : [7, 8, 9],
           "c" : [10, 11, 12]},
        index = [1, 2, 3])
Specify values for each column.
```

```
df = pd.DataFrame(
     [[4, 7, 10],
      [5, 8, 11],
      [6, 9, 12]],
     index=[1, 2, 3],
     columns=['a', 'b', 'c'])
 Specify values for each row.
```

| | | а | b | С |
|---|---|---|---|----|
| n | v | | | |
| d | 1 | 4 | 7 | 10 |
| | 2 | 5 | 8 | 11 |
| е | 2 | 6 | 9 | 12 |

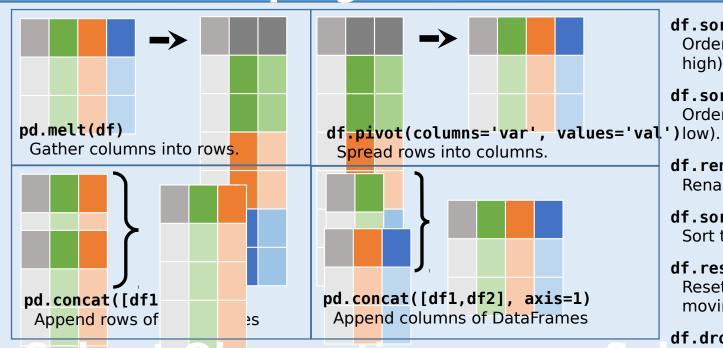

```
df = pd.DataFrame(
          {"a" : [4 ,5, 6],
           "b" : [7, 8, 9],
           "c" : [10, 11, 12]},
index = pd.MultiIndex.from tuples(
          [('d',1),('d',2),
('e',2)],
             names=['n','v']))
```

Chaining

Most pandas methods return a DataFrame so that another pandas method can be applied to the result. This improves readability of code.

as you manipulate variables. No other Each observation and as. is saved in its own

Reshaping Data - Change the layout of a data set

Order rows by values of a column (low to df.sort values('mpg',ascending=False)

Order rows by values of a column (high to

df.rename(columns = {'y':'year'}) Rename the columns of a DataFrame

df.sort index() Sort the index of a DataFrame

df.sort values('mpg')

df.reset index() Reset index of DataFrame to row numbers, moving index to columns.

df.drop(columns=['Length', 'Height'])

Subset Observations

df[df.Length > 7]Extract rows that meet logical criteria.

df.drop duplicates() Remove duplicate rows (only considers columns).

df.head(n) Select first n rows. df.tail(n)

Select last n rows.

df.sample(frac=0.5) Randomly select fraction of rows.

df.sample(n=10) Randomly select n rows. df.iloc[10:20]

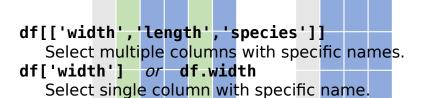

Select rows by position. df.nlargest(n, 'value')

Select and order top n entries.

df.nsmallest(n, 'value') Select and order bottom n

| Logic in Python (and pandas) | | | | | | |
|------------------------------|---------------------|---------------------------------|------------------|--|--|--|
| < | Less than | != | Not equal to | | | |
| > | Greater than | df.column.isin(<i>values</i>) | Group membership | | | |
| == | Equals | pd.isnull(<i>obj</i>) | Is NaN | | | |
| <= | Less than or equals | pd.notnull(<i>obj</i>) | Is not NaN | | | |
| | Greater than or | &, ,~,^,df.any(),df.all(| | | | |

Subset Variables

df.filter(regex='regex') Select columns whose name matches regular expression

| regex (Regular Expressions) Examples | | |
|---|---|--|
| '\.' | Matches strings containing a period '.' | |
| 'Length\$' | Matches strings ending with word 'Length' | |
| '^Sepal' | Matches strings beginning with the word 'Sepal' | |
| '^x[1-5]\$' Matches strings beginning with 'x' and ending with 1,2,3,4,5 | | |
| ''^(?!Species\$).*' Matches strings except the string 'Species' | | |

df.loc[:,'x2':'x4']

Select all columns between x2 and x4 (inclusive).

df.iloc[:,[1,2,5]]

Select columns in positions 1, 2 and 5 (first column is 0).

df.loc[df['a'] > 10, ['a','c']]

Select rows meeting logical condition, and only the

Summarize Data

df['w'].value_counts()

Count number of rows with each unique value of variable

len(df)

of rows in DataFrame.

df['w'].nunique()

of distinct values in a column.

df.describe()

Basic (continuous con

pandas provides a large set of summary functions that operate on different kinds of pandas objects (DataFrame columns, Series, GroupBy, Expanding and Rolling (see below)) and produce single values for each of the groups. When applied to a DataFrame, the result is returned as a pandas Series for each column.

Examples: Sum values of each object.

count()

Count non-NA/null values of each object.

median()

Median value of each object.

quantile([0.25,0.75])

Quantiles of each object.

Minimum value in each object.

max()

Maximum value in each object.

mean()

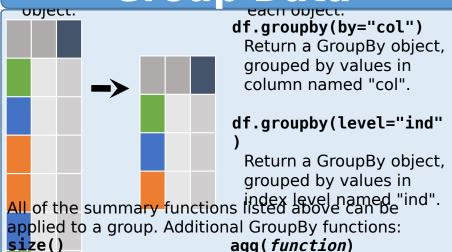

Mean value of each object.

var()

Variance of each object.

Aggregate group using

Group Data

Windows

function.

df.expanding()

Size of each group.

Return an Expanding object allowing summary functions to be applied cumulatively.

df.rolling(n)

Return a Rolling object allowing summary functions to be applied to windows of length n.

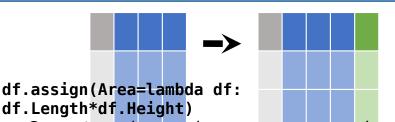

Handling Missing

df.dropna()

Drop rows with any column having NA/null data. df.fillna(value)

Replace all NA/null data with value.

Make New Columns

Compute and append one or more new columns.

df['Volume'] = df.Length*df.Height*df.Depth

Add single column.

pd.qcut(df.col, n, labels=False)

Bin column into n buckets.

Vector functio

pandas provides a large set of vector functions that operate on all columns of a DataFrame or a single selected column (a pandas Series). These functions produce vectors of values for each of the columns, or a single; Series for the individual Saries.) Examples:

Element-wise max. Element-wise min. clip(lower=- abs()

10, upper=10) Absolute value.

Trim values at input
Therexamples below can also be applied to groups. In this case, the function is applied on a per-group basis, and the returned vectors are of the length of the original DataFrame

original DataFrame. shift(-1)

Copy with values shifted by 1.Copy with values lagged

rank(method='dense') by 1.
Ranks with no gaps. cumsum()

rank(method='min')
Cumulative sum.

Ranks. Ties get min rank. cummax()

rank(pct=True) Cumulative max.
Ranks rescaled to interval [0cummin()

1]. Cumulative min.

rank(method='first') cumprod()

Ranks Ties on to first value. Cumulative product

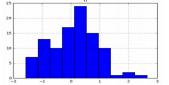

Plotting

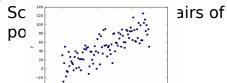

df.plot.hist() df.plot.scatter(x='w',y='h'

Histogram for each column
